

Algorithm 1 Pick- k

```

1: input: set size  $k$ , universe of items  $\mathcal{Y}$ ,  $\alpha, \beta, f(\cdot), g(\cdot)$ 
2:  $Y \leftarrow \{\phi\}$ ,  $n \leftarrow k$ ,  $\alpha' \leftarrow \alpha$ ,  $\beta' \leftarrow \beta$ 
3: while  $n > 0$  do
4:    $M \leftarrow \left\{ \arg \max_s \frac{\alpha'/n + f(s)}{\beta'/n + g(s)} \right\}$  ( $s \in \mathcal{Y} \setminus Y$ )
5:   If  $|M| > n$ , then keep any  $n$  elements in  $M$  and throw away
     the rest
6:    $Y \leftarrow Y \cup M$ 
7:    $\alpha' \leftarrow \alpha' + \sum_{m \in M} f(m)$ 
8:    $\beta' \leftarrow \beta' + \sum_{m \in M} g(m)$ 
9:    $n \leftarrow n - |M|$ 
10: end while
11: output: picked elements  $Y \subseteq \mathcal{Y}$ 

```

We want to optimize the following objective (the X subscripts have been dropped in the interest of clarity):

$$h(Y) = \frac{\alpha + \sum_i f(y_i)}{\beta + \sum_i g(y_i)}, \quad (1)$$

We want to prove that Algorithm 1 picks the optimal solution $Y^* = \arg \max_Y h(Y)$.

Proof of Optimality. For ease of exposition, assume that there are no ties in step 4 and each iteration adds only one element to Y (the proof can be easily extended to cover that case of multiple additions per iteration).

The algorithm maximizes Equation 1 by solving a sequence of sub-problems. Suppose that the set of elements $Y_{(k-n)}^* = \{y_1^*, \dots, y_{k-n}^*\}$ is known to belong to Y^* . Now, for any set $W \subseteq \mathcal{Y} \setminus Y_{(k-n)}^*$ such that W has exactly n elements, we use Equation 1 to get:

$$h(Y_{(k-n)}^* \cup W) = \frac{\alpha + \sum_{y \in Y_{(k-n)}^*} f(y) + \sum_{w \in W} f(w)}{\beta + \sum_{y \in Y_{(k-n)}^*} g(y) + \sum_{w \in W} g(w)} \quad (2)$$

Let $W^* = \arg \max_W h(Y_{(k-n)}^* \cup W)$. Now, we can define the following subproblem:

Problem 1': Given the 4-tuple $(Y_{(k-n)}^*, \alpha, \beta, n)$, find any one element $w^* \in W^*$.

Next, we relate the solution of the sub-problem to the optimal solution Y^* .

LEMMA 1. $w^* \in W^* \Rightarrow w^* \in Y^*$

PROOF. Clearly, $Y^* = Y_{(k-n)}^* \cup W^*$ in order to maximize Equation 1. Since $w^* \in W^*$, we must have $w^* \in Y^*$. \square

LEMMA 2. Problem 1' with the 4-tuple $(Y_{(k-n)}^*, \alpha, \beta, n)$ is equivalent to the 4-tuple

$$\left(\{\phi\}, \alpha + \sum_{y \in Y_{(k-n)}^*} f(y), \beta + \sum_{y \in Y_{(k-n)}^*} g(y), n \right).$$

PROOF. This follows from the form of Equation 2. \square

The optimality of Algorithm 1 can now be proved in two stages. First, assuming the correctness of our solution to each sub-problem, we show that the *sequence* of sub-problems generated by steps 6-9 of our algorithm is correct. Second, we show that each sub-problem is solved correctly (step 4).

THEOREM 1. Assuming that step 4 of Algorithm 1 correctly solves the sub-problem $(\{\phi\}, \alpha', \beta', n)$, the algorithm returns the optimal result Y^* .

PROOF. We show that each iteration adds one new element of Y^* to Y ; as there are k iterations and $|Y^*| = k$, the resulting Y must equal Y^* .

The proof is by induction on the number of iterations $k - n$. In the first iteration ($k - n = 0$), the sub-problem being solved by step 4 is given by $(\{\phi\}, \alpha, \beta, k)$, whose solution is a member of Y^* by Lemma 1.

Suppose the first $k - n$ iterations are correct, and yield $Y_{(k-n)}^* \subset Y^*$. By repeated applications of steps 6-9, we must have $\alpha' = \alpha + \sum_{y \in Y_{(k-n)}^*} f(y)$, and $\beta' = \beta + \sum_{y \in Y_{(k-n)}^*} g(y)$. Thus, the sub-problem for the next iteration, viz. $(\{\phi\}, \alpha', \beta', n)$, is equivalent to $(Y_{(k-n)}^*, \alpha, \beta, n)$ by Lemma 2. Once again, solving this will yield another element of Y^* , by Lemma 1. Hence, at the end of $k - n + 1$ iterations, the set Y contains $k - n + 1$ elements of Y^* ; $Y = Y_{(k-n+1)}^*$, as desired. This completes the proof. \square

Next, we prove the correctness of step 4. Consider one particular iteration, where n elements are yet to be added. For every $y \in \mathcal{Y}$, define $\text{num}(y) = \alpha' / n + f(y)$, $\text{den}(y) = \beta' / n + g(y)$, and $\text{imp}(y) = \text{num}(y) / \text{den}(y)$. We call these the numerator, the denominator, and the importance of element y respectively. We reuse this notation for sets $S \subseteq \mathcal{Y}$ as well: $\text{num}(S) = \sum_{y \in S} f(y)$, $\text{den}(S) = \sum_{y \in S} g(y)$, and $\text{imp}(S) = \text{num}(S) / \text{den}(S)$. Next, we prove an inequality between $\text{imp}(S)$ of any set S and its members, which uses the following fact:

$$\frac{a}{b} > \frac{c}{d} \Rightarrow \frac{a}{b} > \frac{a+c}{b+d} > \frac{c}{d} \quad (b, d > 0) \quad (3)$$

THEOREM 2. Let $S = (s_1, \dots, s_n)$ be an ordered set of size $n \geq 2$ such that $\text{imp}(s_1) < \text{imp}(s_2) < \dots < \text{imp}(s_n)$. Then, $\text{imp}(s_1) < \text{imp}(S) < \text{imp}(s_n)$.

PROOF. We prove $\text{imp}(s_1) < \text{imp}(S)$; the other case is similar. The proof is by induction on n .

When $n = 2$, $\text{imp}(S) = \frac{\text{num}(s_1) + \text{num}(s_2)}{\text{den}(s_1) + \text{den}(s_2)} > \frac{\text{num}(s_1)}{\text{den}(s_1)} = \text{imp}(s_1)$, using Fact 3.

Suppose the proposition is true for all sets of size $n - 1$. Then, for set S of size n , consider the subset $S' = S \setminus \{s_n\}$ of size $n - 1$. We have: $\text{imp}(S) = \frac{\text{num}(S)}{\text{den}(S)} = \frac{\text{num}(S') + \text{num}(s_n)}{\text{den}(S') + \text{den}(s_n)}$. Now, $\frac{\text{num}(S')}{\text{den}(S')} = \text{imp}(S') > \text{imp}(s_1)$, by assumption. Also, $\frac{\text{num}(s_n)}{\text{den}(s_n)} = \text{imp}(s_n) > \text{imp}(s_1)$, by the ordering of set S . From these, it is easily seen that $\text{imp}(S) > \text{imp}(s_1)$. \square

Let $W^* = \{w_1^*, \dots, w_n^*\}$ be the optimal set of n elements that are yet to be selected in accordance with Equation 2, i.e., $Y^* = Y_{(k-n)}^* \cup W^*$. Without loss of generality, let $\text{imp}(w_1^*) < \text{imp}(w_2^*) < \dots < \text{imp}(w_n^*)$. Now, note that step 4 of Algorithm 1 picks the element with the highest importance: $s^* = \arg \max_{s \in \mathcal{Y} \setminus Y} \text{imp}(s)$.

THEOREM 3. Step 4 of Algorithm 1 correctly solves the sub-problem $(\{\phi\}, \alpha', \beta', n)$, i.e., the element selected in step 4 belongs to the optimal solution: $s^* \in W^*$.

PROOF. We have:

$$\begin{aligned} h(Y^*) &= h(Y_{(k-n)}^* \cup W^*) \\ &= \frac{\alpha' + \sum_{i=1}^n f(w_i^*)}{\beta' + \sum_{i=1}^n g(w_i^*)} \\ &= \frac{\sum_{i=1}^n (\alpha' / n + f(w_i^*))}{\sum_{i=1}^n (\beta' / n + g(w_i^*))} \\ &= \text{imp}(W^*) \end{aligned} \quad (4)$$

¹Recall that ties are not being considered here, but can be easily folded into the proof.

This establishes the relationship between the function $h(\cdot)$ that we want to optimize, and the function $\text{imp}(S)$ that we could express using the importances of individual elements $\text{imp}(s)$ where $s \in S$. This only works because the size of the set is n , and we have been using α'/n and β'/n in the $\text{imp}(\cdot)$ function.

Now, suppose $s^* \notin W^*$. Let $W' = W^* \setminus w_1^*$, and $Z = W' \cup \{s^*\} = \{w_2^*, \dots, w_n^*, s^*\}$. Note that Z is again a set of n elements, and hence,

$$h(Y_{(k-n)}^* \cup Z) = \text{imp}(Z) = \frac{\text{num}(W') + \text{num}(s^*)}{\text{den}(W') + \text{den}(s^*)}.$$

Now,

$$\begin{aligned} \frac{\text{num}(W')}{\text{den}(W')} &= \text{imp}(W') \\ &< \text{imp}(w_n^*) && \text{from Thm 2} \\ &< \text{imp}(s^*) && \text{by definition of } s^* \end{aligned} \quad (5)$$

Similarly,

$$\begin{aligned} \frac{\text{num}(W')}{\text{den}(W')} &= \text{imp}(W') \\ &> \text{imp}(w_2^*) && \text{from Thm 2} \\ &> \text{imp}(w_1^*) \end{aligned} \quad (6)$$

Thus, we have:

$$h(Y^*) = \text{imp}(W^*) = \frac{\text{num}(w_1^*) + \text{num}(W')}{\text{den}(w_1^*) + \text{den}(W')} < \frac{\text{num}(W')}{\text{den}(W')},$$

where we use Equation 6 and Fact 3. Similarly,

$$h(Y_{(k-n)}^* \cup Z) = \text{imp}(Z) = \frac{\text{num}(W') + \text{num}(s^*)}{\text{den}(W') + \text{den}(s^*)} > \frac{\text{num}(W')}{\text{den}(W')},$$

using Equation 5 and Fact 3. Hence,

$$h(Y^*) < \frac{\text{num}(W')}{\text{den}(W')} < h(Y_{(k-n)}^* \cup Z),$$

implying that Y^* is not the optimal solution, which is a contradiction. Hence, $s^* \in W^*$. \square
